

1 ABSTRACT

2

3 A medical imaging system comprises a patient support surface. An imaging apparatus has a
4 support table located within the support surface, and adjustable relative to the support surface to
5 be located above the surface and thereby engage a portion of the patient to be imaged. The
6 imaging is performed by a rotary scanner rotatable about a vertical axis utilises multiple
7 transducers that each image a different portion to produce conical slice. The signal processing
8 compensates for attenuation and different gains in the transducers to provide a normalised set f
9 data for reconstruction.
